Example: Weather HMM

- An HMM is defined by:
 - Initial distribution: $P(X_1)$
 - Transitions: $P(X_t \mid X_{t-1})$
 - Emissions: $P(E_t \mid X_t)$

R _t	R _{t+1}	$\begin{array}{c} P(R_{t+1} \\R_t) \end{array}$
+r	+r	0.7
+r	-r	0.3
-r	+r	0.3
-r	-r	0.7

R_{t}	U _t	$P(U_t R_t)$
+r	+u	0.9
+r	-u	0.1
-r	+u	0.2
-r	-u	0.8

Filtering / Monitoring

- Filtering, or monitoring, is the task of tracking the distribution $B_t(X) = P_t(X_t \mid e_1, ..., e_t)$ (the belief state) over time
- We start with B₁(X) in an initial setting, usually uniform
- As time passes, or we get observations, we update B(X)
- The Kalman filter was invented in the 60's and first implemented as a method of trajectory estimation for the Apollo program

Inference: Base Cases

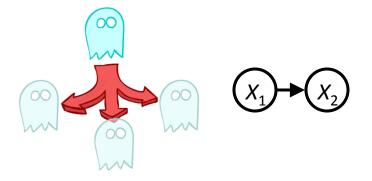

$$P(X_1|e_1)$$

$$P(x_1|e_1) = P(x_1, e_1)/P(e_1)$$

$$\propto_{X_1} P(x_1, e_1)$$

$$= P(x_1)P(e_1|x_1)$$

$$P(X_2)$$

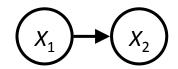

$$P(x_2) = \sum_{x_1} P(x_1, x_2)$$

$$= \sum_{x_1} P(x_1) P(x_2 | x_1)$$

Passage of Time

Assume we have current belief P(X | evidence to date)

$$B(X_t) = P(X_t|e_{1:t})$$

Then, after one time step passes:

$$P(X_{t+1}|e_{1:t}) = \sum_{x_t} P(X_{t+1}, x_t|e_{1:t})$$

$$= \sum_{x_t} P(X_{t+1}|x_t, e_{1:t}) P(x_t|e_{1:t})$$

$$= \sum_{x_t} P(X_{t+1}|x_t) P(x_t|e_{1:t})$$

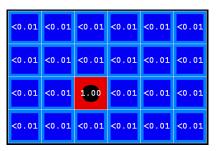

Or compactly:

$$B'(X_{t+1}) = \sum_{x_t} P(X'|x_t)B(x_t)$$

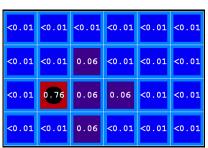

- Basic idea: beliefs get "pushed" through the transitions
 - With the "B" notation, we have to be careful about what time step t the belief is about, and what evidence it includes

Example: Passage of Time

As time passes, uncertainty "accumulates"

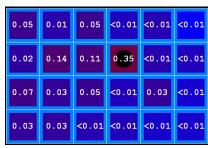

T = 1

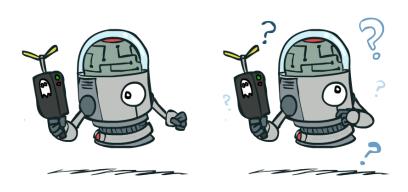

T = 2

(Transition model: ghosts usually go clockwise)

T = 5

Observation

Assume we have current belief P(X | previous evidence):

$$B'(X_{t+1}) = P(X_{t+1}|e_{1:t})$$

Then, after evidence comes in:

$$P(X_{t+1}|e_{1:t+1}) = P(X_{t+1}, e_{t+1}|e_{1:t})/P(e_{t+1}|e_{1:t})$$

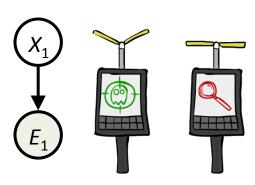

$$\propto_{X_{t+1}} P(X_{t+1}, e_{t+1}|e_{1:t})$$

$$= P(e_{t+1}|e_{1:t}, X_{t+1})P(X_{t+1}|e_{1:t})$$

$$= P(e_{t+1}|X_{t+1})P(X_{t+1}|e_{1:t})$$

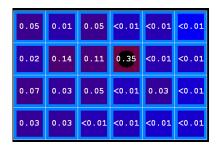

$$B(X_{t+1}) \propto_{X_{t+1}} P(e_{t+1}|X_{t+1})B'(X_{t+1})$$

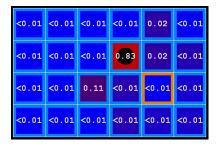

- Basic idea: beliefs "reweighted" by likelihood of evidence
- Unlike passage of time, we have to renormalize

Example: Observation

• As we get observations, beliefs get reweighted, uncertainty "decreases"

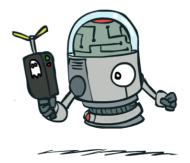

After observation

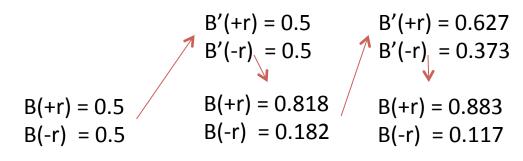

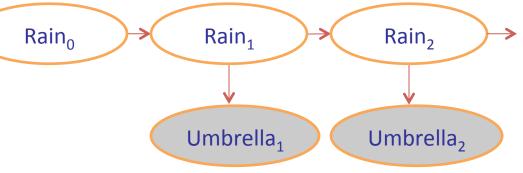

Example: Weather HMM

R _t	R _{t+1}	$P(R_{t+1} R_t)$
+r	+r	0.7
+r	-r	0.3
-r	+r	0.3
-r	-r	0.7

R_{t}	U _t	$P(U_t R_t)$
+r	+u	0.9
+r	-u	0.1
-r	+u	0.2
-r	-u	0.8

The Forward Algorithm

We are given evidence at each time and want to know

$$B_t(X) = P(X_t | e_{1:t})$$

We can derive the following updates

$$P(x_{t}|e_{1:t}) \propto_{X} P(x_{t}, e_{1:t})$$

$$= \sum_{x_{t-1}} P(x_{t-1}, x_{t}, e_{1:t})$$

$$= \sum_{x_{t-1}} P(x_{t-1}, e_{1:t-1}) P(x_{t}|x_{t-1}) P(e_{t}|x_{t})$$

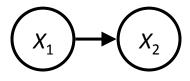

$$= P(e_{t}|x_{t}) \sum_{x_{t-1}} P(x_{t}|x_{t-1}) P(x_{t-1}, e_{1:t-1})$$

We can normalize as we go if we want to have P(x| e) at each time step, or just once at the end...

Online Belief Updates

- Every time step, we start with current P(X | evidence)
- We update for time:

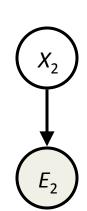

$$P(x_t|e_{1:t-1}) = \sum_{x_{t-1}} P(x_{t-1}|e_{1:t-1}) \cdot P(x_t|x_{t-1})$$

We update for evidence:

$$P(x_t|e_{1:t}) \propto_X P(x_t|e_{1:t-1}) \cdot P(e_t|x_t)$$

The forward algorithm does both at once (and doesn't normalize)

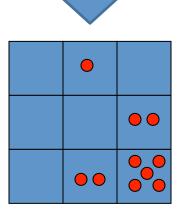

Exercise: HMM filtering, prediction

- Get code from Piazza
 hmm-example.zip posted today in Resources
- Fill in HMM filter, predict methods
- Can work in groups of 2 or 3
- (Will go over structure)

Particle Filtering

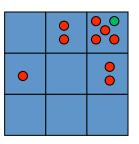

- Filtering: approximate solution
- Sometimes |X| is too big to use exact inference
 - |X| may be too big to even store B(X)
 - E.g. X is continuous
- Solution: approximate inference
 - Track samples of X, not all values
 - Samples are called particles
 - Time per step is linear in the number of samples
 - But: number needed may be large
 - In memory: list of particles, not states
- This is how robot localization works in practice
- Particle is just new name for sample

0.0	0.1	0.0
0.0	0.0	0.2
0.0	0.2	0.5

Representation: Particles

- Our representation of P(X) is now a list of N particles (samples)
 - Generally, N << |X|
 - Storing map from X to counts would defeat the point

- P(x) approximated by number of particles with value x
 - So, many x may have P(x) = 0!
 - More particles, more accuracy
- For now, all particles have a weight of 1

Particles:

Particle Filtering: Elapse Time

 Each particle is moved by sampling its next position from the transition model

$$x' = \text{sample}(P(X'|x))$$

- This is like prior sampling samples' frequencies reflect the transition probabilities
- Here, most samples move clockwise, but some move in another direction or stay in place
- This captures the passage of time
 - If enough samples, close to exact values before and after (consistent)

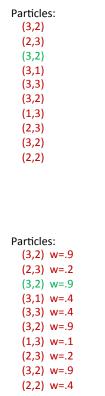

Particle Filtering: Observe

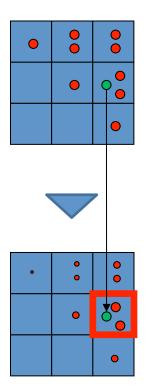

Slightly trickier:

- Don't sample observation, fix it
- Similar to likelihood weighting, downweight samples based on the evidence

$$w(x) = P(e|x)$$
$$B(X) \propto P(e|X)B'(X)$$

 As before, the probabilities don't sum to one, since all have been downweighted (in fact they now sum to (N times) an approximation of P(e))

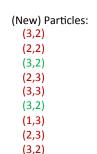

Particle Filtering: Resample

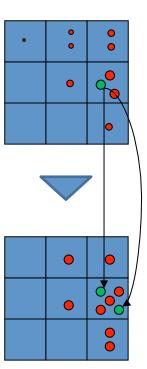

- Rather than tracking weighted samples, we resample
- N times, we choose from our weighted sample distribution (i.e. draw with replacement)
- This is equivalent to renormalizing the distribution
- Now the update is complete for this time step, continue with the next one

(3,2) w=.9 (2,3) w=.2 (3,2) w=.9 (3,1) w=.4 (3,3) w=.4 (3,2) w=.9 (1,3) w=.1 (2,3) w=.2 (3,2) w=.9 (2,2) w=.4

Particles:

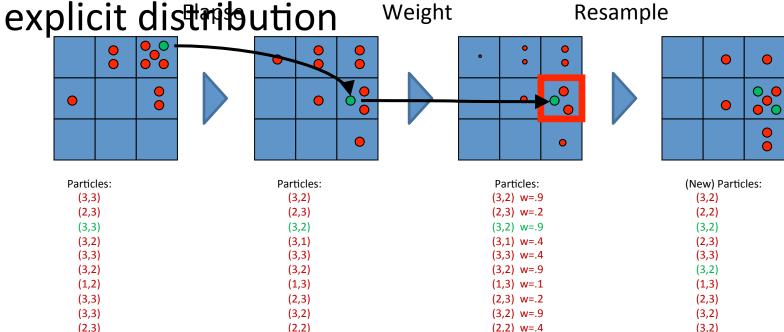

(3,2)

Recap: Particle Filtering

• Particles: track samples of states rather than an explicit distribution Weight Resample

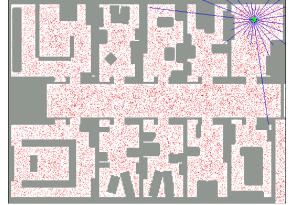

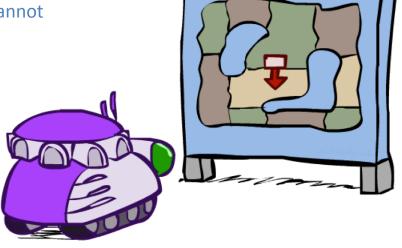

Robot Localization

In robot localization:

- We know the map, but not the robot's position
- Observations may be vectors of range finder readings
- State space and readings are typically continuous (works basically like a very fine grid) and so we cannot store B(X)

Particle filtering is a main technique
